LISTING OF CLAIMS

Claim 1 (currently amended) – An orthopedic device, comprising, in combination:

a threaded shaft said shaft having one terminus <u>provided</u> with rotational means about a single axis transverse to a long axis of said threaded shaft and means to prohibit all other rotation,

a cup having an upper end with interior threads and having a lower rotational means receiving area dimensioned to allow rotation of said threaded shaft about said one terminus and about a single axis transverse to a long axis of said threaded shaft and means to prohibit all other rotation,

said cup having a transverse slot,

a rod passing through said slot and abutting said rotational means in proximate tangential registry,

and <u>bolt</u> means <u>threaded to said cup's interior threads</u> to fix said rod and said threaded shaft into a fixed position relative to said cup.

Claim 2 (original) - The device of claim 1 wherein said threaded shaft has first and second thread patterns thereon.

Claim 3 (currently amended) - A method for supporting a skeletal structure, the steps including:

deploying a plurality of fasteners within a plurality of support cups;

screwing the fasteners into a bone to be mended such that the bone is subjected to both axially compressive and radially inward forces relative to the fastener;

My

deploying a support rod within the support cups;

orienting the cups relative to the rods so the rod abuts the fasteners;

and fixing the rod and fasteners together by inducing a radially inward force on the cups.

Claim 4 (original) - The device of claim 2 wherein said threaded shaft first and second thread patterns have differing thread pitch, such that said second thread pattern has finer threads than said first thread pattern.

Claim 5 (original) - The device of claim 4 wherein said thread patterns have crests which are axially offset from their respective roots, inducing a radially inward directed force.

Claim 6 (currently amended) - The device of claim 5 wherein said first and second thread crests face each other inducing compressive free force axially.

Claim 7 (new) - An orthopedic stabilization device, comprising, in combination:

a threaded shaft having both axial and radial bone engaging compressive threads.

said shaft having a free end terminating in a disc constrained within a cup having a recess complemental to said disc to permit relative rotation of said cup and said shaft about a geometrical center of said disc,

a rod received within said cup and a tangential registry with said disc, and means to hold said rod, cup and disc in fixed relationship.

Claim 8 (new) - An orthopedic stabilization device, comprising in combination:

a cup having a recess for receiving a threaded shaft, said cup recess and said shaft including means to permit shaft rotation only in one plane, said cup having an interior thread on a portion of said recess which is not addressing said threaded shaft,

said interior thread having a thread pattern complemental to a bolt such that when said bolt is threadly engaged in said interior thread and said bolt reaches its limit of travel, a radially inward force is applied to said interior thread.

Claim 9 (new) - The device of claim 8 wherein said bolt includes a stem projecting away from said cup, said stem operatively coupled to a clamp with means to adjust the position of said clamp along said stem,

and a rod adjustably disposed within said clamp.

Claim 10 (new) - The device of claim 8 wherein said threaded shaft includes two thread patterns similar to said bolt and interior thread, said two thread patterns facing each other and one having a finer pitch than the other.

Claim 11 (new) - The device of claim 9 when said threaded shaft includes two thread patterns similar to said bolt and interior thread, said two thread patterns facing each other and one having a finer pitch than the other.
